30.04.2015

Byteasar is a programmer who works on a revolutionary text editor. In the editor there are two types of operations: one type allows to *edit text* in the editor, and the other type allows to *undo* previously performed operations. One of the innovative features of this editor is a *multilevel undo operation*. It works as follows. We say that a text editing operation is an operation of *level 0*. An *undo operation of level  $i$*  (for  $i = 1, 2, \dots$ ) undoes the last operation of level at most  $i - 1$  which is not undone. For instance, an undo operation of level 1 can undo only editing operations, and an undo operation of level 2 can undo editing operations as well as undo operations of level 1 (but no undo operations of greater levels).

More formally, each of the already performed operations can be in two states: **active** or **undone**. Let  $X$  be one of the operations. Just after performing the operation  $X$ , it is in the state **active**. If  $X$  is an undo operation of level  $i$ , we find the most recent operation in state **active** of level at most  $i - 1$  (denote it by  $X_1$ ) and change the state of the operation  $X_1$  to **undone**. If  $X_1$  is also an undo operation, we must change to **active** the state of the operation which  $X_1$  had undone (say  $X_2$ ). We continue in the same manner: whenever the state of an undo operation  $X_j$  which had previously undone some operation  $X_{j+1}$  changes, we must also change the state of the operation  $X_{j+1}$  (which, of course, may result in changing states of further operations). The whole chain of state modifications finishes when an editing operation is reached.

For simplicity, the current contents of text in the editor will be specified by a single integer  $s$ , called the *editor state* (equal to 0 at the beginning). Each editing operation specifies the editor state that it produces. The editor state depends on the last editing operation in the state **active**. Help Byteasar and write a program which keeps track of the editor state.

Let us see this in action: the following table shows some operations performed by Byteasar and the editor state after performing each of them. The symbol  $E_s$  denotes an editing operation which changes the editor state to  $s$ , whereas the symbol  $U_i$  denotes an undo operation of level  $i$ .

Operation	$E_1$	$E_2$	$E_5$	$U_1$	$U_1$	$U_3$	$E_4$	$U_2$	$U_1$	$U_1$	$E_1$	
Editor state	0	1	2	5	2	1	2	4	2	1	0	1

First, Byteasar performed three editing operations. The editor state changed from 0 to 1, then to 2, and finally to 5. Next, he performed two undo operations of level 1, which undid the operations  $E_5$  and  $E_2$  (changing their state to **undone**). Thus the editor state was restored to 1. The following undo operation of level 3 undid the last operation  $U_1$  (changing its state to **undone**), consequently restoring the operation  $E_2$  (changing its state back to **active**). As a result the editor state changed once again to 2. Operation  $U_2$  undid the operation  $E_4$ , operation  $U_1$  once again undid the restored operation  $E_2$ , the last operation  $U_1$  undid the operation  $E_1$ , and the final operation is  $E_1$ .

## Input

The first line of the input contains a positive integer  $n$ , specifying the number of operations performed by Byteasar. The next  $n$  lines contain descriptions of operations, one per line, each being an integer  $a_i$  ( $-n \leq a_i \leq n$ ,  $a_i \neq 0$ ). If  $a_i > 0$ , then it specifies an editing operation which modifies the editor state to  $a_i$ . If  $a_i < 0$ , then it specifies an undo operation of level  $-a_i$ . You can assume that for every undo operation there will be some operation in the state **active** of smaller level to undo.

v. 3

Editor 1/2

## Output

Your program should output  $n$  lines. The  $i$ -th line should contain one integer specifying the editor state after performing the first  $i$  operations from the input.

## Examples

For the input data:

11  
1  
2  
5  
-1  
-1  
-3  
4  
-2  
-1  
-1  
1

a correct result is:

1  
2  
5  
2  
1  
2  
4  
2  
1  
0  
1

## Grading

Subtask	Conditions	Points
1	$n \leq 5000$	20
2	$n \leq 300\,000$ and there are only operations $E_i$ and $U_1$	15
3	$n \leq 300\,000$ and only the last number in the sequence is graded (however, the first $n - 1$ numbers must be integers ranging from 0 to $n$ )	28
4	$n \leq 300\,000$	37
